Abstract

Previous work on network coding capacity for random wired and wireless networks have focused on the case where the capacities of links in the network are independent. In this paper, we consider a more realistic model, where wireless networks are modelled by random geometric graphs with interference and noise. In this model, the capacities of links are not independent. By employing coupling and martingale methods, we show that, under mild conditions, the network coding capacity for random wireless networks still exhibits a concentration behavior around the mean value of the minimum cut.

I. INTRODUCTION

Traditionally, information flow in networked systems was treated like fluid through pipes, and independent information flows were processed separately. Under this assumption, for a unicast transmission (one source node transfers information to one destination node), the maximum transmission rate is bounded by the size of the minimum cut between the source and the destination. This result is known as the *Min-Cut Max-Flow Theorem*, which was proved by Menger [1], Ford and Fulkerson [2] and Elias *et al.* [3]. However, for a multicast transmission (one source node transfers information to multiple destination nodes), this maximum flow rate cannot always be achieved by traditional store-and-forward routing algorithms, even if each source-destination pair has the minimum cut with the same size. That is because in a multicast transmission, some links in the network may be shared by the routing paths for different source-destination pairs.

In their seminal paper [4], Ahlswede *et al.* proposed a *network coding* scheme, and showed that if we allow intermediate nodes to encode their received messages and forward the coded messages to their next-hop neighbors, the maximum flow rate can be achieved for multicast transmissions. In addition to the information theoretic treatment of [4], network coding has also been studied in an algebraic framework developed by Koetter and Médard in [5], and a combinatorial framework proposed by Fragouli and Soljanin in [6]. Code design for network coding schemes has also attracted intense interest. In [7], Li *et*

al. showed that linear codes are sufficient to achieve the maximum flow rate for a one-source multicast transmission. Koetter and Médard, and Jaggi *et al.* constructed linear multicast codes for network coding schemes in [5] and in [8], respectively. The approach of constructing linear codes in a randomized way for multicast transmissions was proposed by Ho *et al.* in [9]. For a detailed review of network coding and its applications in many fields, e.g., wireless communication, content distribution, security, please see the book by Fragouli and Soljanin [10].

In most studies on network coding, network topologies are assumed to be known. In [11], [12], Ramamoorthy *et al.* studied network coding capacity for weighted random graphs and random geometric graphs. In the random graph model, each pair of nodes are connected by a bidirectional link with probability $p < 1$ independently [13], [14]. The capacity of each link is assumed to be i.i.d. according to some probability distribution. In the random geometric graph model, two nodes are connected to each other by a bidirectional link only when their distance is less than or equal to a predefined positive value r , the characteristic radius [15]. Each link has a unit capacity. For these two types of random networks, the authors showed that the network coding capacity is concentrated at the (weighted) mean degree of the graph, i.e., the (weighted) mean number of neighbors of each node. Essentially, the results reveal a concentration behavior of the size of the minimum cut between two nodes in random graphs or random geometric graphs. Related problems have been studied in the literature, e.g., [16] and references therein. In [17], the authors studied a generalized random geometric graph model, where two nodes are connected by a bidirectional link with probability 1 if their distance d is less than or equal to $r_0 > 0$, and with probability $p < 1$ if $r_0 < d \leq r_1$. They obtained similar concentration results.

The geometric models in [11], [12], [17] assume that a link exists (possibly with a probability) between two nodes when the nodes are within each other's transmission range. Although each link has a direction, as all links are bidirectional (i.e., the link (i, j) implies the existence of the link (j, i)), the model in fact leads to an *undirected* graph and considerably simplifies the resulting analysis. In addition, interference among wireless terminals was not considered in [11], [12], [17]. Nevertheless, in wireless networks, due to noise, interference, and the heterogeneity of transmission powers, significantly more sophisticated models for link connectivity are needed. For instance, a widely-used model for wireless communication channels is the Signal-to-Interference-and-Noise-Ratio (SINR) model [18], [19]. In this paper, we study the capacity, i.e., the size of the minimum cut, of random wireless networks under the SINR model.

Given that network coding capacity with noisy links is in general still an open problem, we assume that as long as the SINR β_{ij} of a link (i, j) is greater than or equal to a predefined threshold β , then node i can transmit data at rate R packets/sec to node j without error. That is, links are noise-free once the SINR condition is met. In other words, we view network coding as operating on a higher layer in the network communication stack, and assume there is an error correcting code at the lower layer which corrects errors on the links once the SINR threshold is met. Given this model, each link is indeed directional, and

the capacities of different links are not independent. Nevertheless, we will show that under some mild conditions, the capacity still has a sharp concentration when the scale of the network is large enough.

It is worthy mentioning that the capacity we investigate in this paper is different from the one studied in [20]–[25]. The latter is referred to as throughput capacity, or transport capacity, for random wireless networks with many-to-many transmissions. In other words, it is the maximum achievable averaged rate at which each node in the network can transmit (simultaneously with other nodes specified by scheduling schemes) to a randomly selected destination node. In contrast, the network coding capacity that we study in this paper (as in [11], [12], [17]) is the maximum rate that one source can achieve in a multicast transmission, which is determined by the size of the minimum cut between the source and the destinations.

This paper is organized as follows. In Section II, we describe the random wireless network model. In Section III, we study the network coding capacity for a single source and multiple destinations. Specifically, we investigate two cases. In the first case, all nodes have the same transmission power, and in the second case, the transmission powers are heterogeneous. We use different techniques for these two cases and show that the network coding capacity has a concentration behavior in both cases. In Section IV, we present relevant simulation results, and finally, we conclude in Section V.

II. RANDOM WIRELESS NETWORK MODEL

We use the following model for random wireless networks. Assume

- (i) $\mathcal{X} = \{\mathbf{X}_1, \mathbf{X}_2, \dots, \mathbf{X}_n\}$ is a set of n nodes which are independently and uniformly distributed at random on the two-dimensional unit torus, where $\mathbf{X}_i$ denotes the random location of node i , and n is the total number of nodes.
- (ii) Each node i has a transmission power P_i , which follows a probability distribution $f_P(p)$, $p \in [p_{\min}, p_{\max}]$, where $0 < p_{\min} \leq p_{\max} < \infty$.

Here, the existence of a link from node i to node j depends on j 's ability to decode the transmitted signal from i , which is in turn determined by the Signal-to-Interference-and-Noise-Ratio (SINR) given by

$$\beta_{ij} = \frac{P_i L(d_{ij})}{N_0 + \gamma \sum_{k \neq i, j} P_k L(d_{kj})}, \quad (1)$$

where P_i is the transmission power of node i , d_{ij} is the distance between nodes i and j , and N_0 is the power of background noise. The parameter γ is the inverse of the system processing gain. It is equal to 1 in a narrow-band system and smaller than 1 in a broadband (e.g., CDMA) system. The signal attenuation function $L(\cdot)$ is a function of the distance $d_{ij} = \|\mathbf{X}_i - \mathbf{X}_j\|$, where $\|\cdot\|$ is the Euclidean norm, and is usually given by $L(d_{ij}) = c d_{ij}^{-\alpha}$ for some constants c and $2 < \alpha < 4$.

Under the SINR model, the transmitted signal of node i can be decoded at j if and only if $\beta_{ij} > \beta$, where β is some threshold for decoding. In this case, a link (i, j) from i to j is said to exist. Note that even if $\beta_{ij} > \beta$, $\beta_{ji} > \beta$ may not hold and thus the link (j, i) may not exist. Thus, the graph resulting

from the SINR model is in general *directed*. It is clear that link (i, j) is bidirectional if and only if $\min\{\beta_{ij}, \beta_{ji}\} > \beta$. Denote by $G(\mathcal{X}, \mathcal{P}, \gamma)$ the ensemble of random wireless networks induced by the above physical model, where $\mathcal{P} = \{P_1, P_2, \dots, P_n\}$ represents the set of transmission powers.

For transmission power P and signal attenuation function $L(\cdot)$, we assume

- (i) $p_{\min} > \beta N_0$;
- (ii) $\Pr(P = p_{\min}) > 0, \Pr(P = p_{\max}) > 0$,
- (iii) $L(x)$ is continuous and strictly decreasing in x

for technical and practical reasons. In the remainder of this paper, under different circumstances, we may place further constraints on P_i .

The sum $\sum_{k \neq j} L(d_{kj}) = \sum_{k \neq j} L(\|\mathbf{X}_k - \mathbf{X}_j\|)$ is a random variable depending on the locations of all nodes in the network. Define, for all $j = 1, \dots, n$,

$$J(j) \triangleq \sum_{k \neq j} L(d_{kj}), \quad (2)$$

$$I(j) \triangleq \sum_{k \neq j} P_k L(d_{kj}). \quad (3)$$

To study the asymptotic network capacity, we will let the number of nodes n go to infinity. Since the region is fixed, this corresponds to a dense network model [15], [20]. Another widely used model is the extended network model [26], [27], in which the number of nodes and the area of the region both go to infinity while the ratio between them—the density of the network, is kept constant. Both models are widely used in the literature. We will focus on the former one in this paper.

III. NETWORK CODING CAPACITY FOR SINGLE SOURCE TRANSMISSION

A. Capacity of a Cut

Let C_{ij} be the capacity of a link (i, j) . We will specify the form of C_{ij} later for different scenarios. Consider a single-source multiple-destination transmission problem. Let s be the source node. Suppose there are l destination nodes, $t_1, \dots, t_l$, and m relay nodes, $u_1, \dots, u_m$. Denote the set of the destination nodes and relay nodes by $\mathcal{T}$ and $\mathcal{R}$, respectively. Note that $\{s\}, \mathcal{T}$ and $\mathcal{R}$ are all subsets of $\mathcal{X}$. In this paper, we always assume that there are no direct links between the source and its destinations. Fig. 1 gives an example of single-source single-destination transmission.

Let the capacity of the link from the source s to each relay node u_i be C_{si} , $i = 1, \dots, m$, the capacity from relay node u_i to another relay node u_j be C_{ij} , $i \neq j$, $i = 1, \dots, m$, $j = 1, \dots, m$, and the capacity from each relay node u_i to each destination node t_j be C_{it_j} , $i = 1, \dots, m$, $j = 1, \dots, l$. Unlike random geometric graph models studied in [11], [12], [17], the capacities in our model are not symmetric (i.e., $C_{ij} \neq C_{ji}$) nor independent in general.

Fig. 1. Single-source single-destination transmission in directed SINR graphs

In our SINR wireless network model, there are two sources of randomness: one is the random location of each node and the other is the random transmission power of each node. We use E_X and E_P to denote the expectation operation with respect to each probability measure, respectively.

Let $\bar{C}$ be the expected capacity of a link (i, j) , defined as

$$\begin{aligned}\bar{C} &= E_X E_P[C_{ij}] \\ &= \int_0^\infty C_{ij} dF_{\beta_{ij}}(\tau),\end{aligned}\tag{4}$$

where $F_{\beta_{ij}}(\cdot)$ is the c.d.f. of β_{ij} , which is determined by $f_P(\cdot)$, the distribution of $\mathcal{X}$, and the path-loss function $L(\cdot)$.

Now define an s - t -cut of size k for a given source s and destination $t \in \mathcal{T}$ as a partition of the relay nodes into two subsets V_k and V_k^c , such that $|V_k| = k$, $|V_k^c| = m - k$, $V_k \cup V_k^c = \mathcal{R}$ and $V_k \cap V_k^c = \emptyset$. An example of an s - t -cut is shown in Fig. 2. Let

$$C_k = \sum_{u_i \in V_k^c} C_{si} + \sum_{u_j \in V_k} \sum_{u_i \in V_k^c} C_{ji} + \sum_{u_j \in V_k} C_{jt},\tag{5}$$

then C_k is the capacity of the corresponding s - t -cut. Although C_k is a sum of dependent but identically distributed random variables, we still have

$$\begin{aligned}E[C_k] &= E_X E_P[C_k] \\ &= \sum_{u_i \in V_k^c} E_X E_P[C_{si}] + \sum_{u_j \in V_k} \sum_{u_i \in V_k^c} E_X E_P[C_{ji}] + \sum_{u_j \in V_k} E_X E_P[C_{jt}] \\ &= [m + k(m - k)]\bar{C},\end{aligned}\tag{6}$$

and consequently $E[C_k] = E[C_{m-k}]$ for $k = 0, 1, \dots, m$, and $E[C_0] \leq E[C_1] \leq \dots \leq E[C_{\lceil m/2 \rceil}]$.

To show that the capacity of any source-destination pair concentrates at some value, we will first show that for such a source-destination pair, the capacity of any s - t -cut of size k concentrates at its mean value.

Fig. 2. An s - t cut for the single-source single-destination transmission in directed SINR graphs

Similar results were proved in [11], [12], [17], where the capacities of the links that originate from the same node are i.i.d. Nevertheless, the methods used in [11], [12], [17] do not apply here, since in the SINR model, C_k is a sum of dependent random link capacities. Instead, we employ coupling, martingale methods and Azuma's inequality [15], [28] to solve the problem.

Note that when $\gamma = 0$, i.e., there is no interference in the network, the capacities C_{si} for $i = k+1, \dots, m$, are mutually independent; so are the capacities C_{ij} for any fixed $i = 1, \dots, k$ with $j = k+1, \dots, m$ or t . In this case, although the link capacities are still asymmetric, $\sum_{u_i \in V_k^c} C_{si}$ and $\sum_{u_i \in V_k^c \cup \{t\}} C_{ji}$ for $j \in V_k$ become sums of independent random variables. Thus we can apply methods similar to those used in [11], [12], [17] to obtain the same concentration results.

B. Constant Transmission Power

Consider the scenario when all nodes transmit with a constant power P_0 and denote the corresponding model by $G(\mathcal{X}, P_0, \gamma)$. In this case, the SINR of link (i, j) can be rewritten as

$$\begin{aligned} \beta_{ij} &= \frac{L(d_{ij})}{N_0/P_0 + \gamma \sum_{k \neq i,j} L(d_{kj})} \\ &= \frac{L(d_{ij})}{N_0/P_0 + \gamma J(j) - \gamma L(d_{ij})}. \end{aligned} \quad (7)$$

Assume that when $\beta_{ij} \geq \beta$, the link (i, j) has capacity R , i.e., node i can transmit data at rate R packets/sec to node j without error. Then, we can define C_{ij} as

$$C_{ij} = \begin{cases} R & \beta_{ij} \geq \beta, \\ 0 & \beta_{ij} < \beta. \end{cases} \quad (8)$$

Note that when the wireless channel is an additive Gaussian channel, the capacity of link (i, j) is [29]

$$C_{ij} = \begin{cases} \frac{1}{2} \log(1 + \beta_{ij}) & \beta_{ij} \geq \beta, \\ 0 & \beta_{ij} < \beta. \end{cases} \quad (9)$$

Our results in this subsection do not depend on any particular form of C_{ij} when $\beta_{ij} \geq \beta$. Nevertheless, since we consider the application of network coding, it would be more appropriate to focus on (8), rather than (9).

Note that β_{ij} and thus C_{ij} , are determined by $L(d_{ij})$ and $J(j)$. Because of the i.i.d. distribution of the $\mathbf{X}_i$'s, given $\mathbf{X}_j$, the d_{ij} 's are independent for all $i \neq j$. Given node j , let

$$E[L] \triangleq E_{\mathbf{X}_i}[L(d_{ij})], \quad (10)$$

then

$$E[J(j)] = E\left[\sum_{i \neq j} L(d_{ij})\right] = (n-1)E[L] \triangleq E[J]. \quad (11)$$

Since our model is a dense network model and the area of the region is fixed, $E[L] = E[L(d_{ij})]$ is a constant and $E[J] = (n-1)E[L]$ scales with n . For different j 's, it is clear that $J(j)$'s are not independent. However, they have the same sharp concentration behavior in large-scale wireless networks. This is established in the following lemma.

Lemma 1: Suppose there are n nodes in the network, then

$$\Pr(J(j) \leq (1 - \epsilon_1)E[J]) = O\left(\frac{1}{n^2}\right), \quad (12)$$

and

$$\Pr(J(j) \geq (1 + \epsilon'_1)E[J]) = O\left(\frac{1}{n^2}\right), \quad (13)$$

for all $j = 1, 2, \dots, n$, where $\epsilon_1 = \sqrt{\frac{4 \ln n}{(n-1)E[L]}}$ and $\epsilon'_1 = \sqrt{\frac{6 \ln n}{(n-1)E[L]}}$.

Proof: Given any node j , because $J(j) = \sum_{i \neq j} L(d_{ij})$, and $L(d_{ij})$ are i.i.d. for all $i \neq j$, by the Chernoff bound [28], [30], we have

$$\begin{aligned} \Pr(J(j) \leq (1 - \epsilon_1)E[J]) &\leq \exp\left\{-\frac{E[J]\epsilon_1^2}{2}\right\} \\ &= \exp\left\{-\frac{(n-1)E[L]\epsilon_1^2}{2}\right\}, \end{aligned} \quad (14)$$

and

$$\begin{aligned} \Pr(J(j) \geq (1 + \epsilon'_1)E[J]) &\leq \exp\left\{-\frac{E[J]\epsilon_1'^2}{3}\right\} \\ &= \exp\left\{-\frac{(n-1)E[L]\epsilon_1'^2}{3}\right\}. \end{aligned} \quad (15)$$

Substituting $\epsilon_1 = \sqrt{\frac{4 \ln n}{(n-1)E[L]}}$ and $\epsilon'_1 = \sqrt{\frac{6 \ln n}{(n-1)E[L]}}$ into (14) and (15), we obtain (12) and (13), respectively. $\square$

Lemma 1 shows that when the network is large, i.e., n is sufficiently large, $J(j)$ concentrates at $\gamma(n-1)E[L] = \Theta(n)E[L]$. The reason for this is the uniform distribution of the nodes.

Now define two other types of SINR models $G'(\mathcal{X}, P_0, \gamma)$ and $G''(\mathcal{X}, P_0, \gamma)$ which are coupled with $G(\mathcal{X}, P_0, \gamma)$ such that they have the same point process $\mathcal{X}$ and constant power P_0 . Let the SINR of link (i, j) in $G'(\mathcal{X}, P_0, \gamma)$ and $G''(\mathcal{X}, P_0, \gamma)$ be

$$\beta'_{ij} = \frac{L(d_{ij})}{N_0/P_0 + (1 + \epsilon'_1)\gamma E[J] - \gamma L(d_{ij})} \quad (16)$$

and

$$\beta''_{ij} = \frac{L(d_{ij})}{N_0/P_0 + (1 - \epsilon_1)\gamma E[J] - \gamma L(d_{ij})}, \quad (17)$$

respectively.

Let C'_{ij} and C''_{ij} be the capacity of link (i, j) in $G'(\mathcal{X}, P_0, \gamma)$ and $G''(\mathcal{X}, P_0, \gamma)$, respectively. Since $\epsilon_1 \rightarrow 0$ and $\epsilon'_1 \rightarrow 0$ as $n \rightarrow \infty$, C'_{ij} and C''_{ij} are asymptotically equal to C_{ij} .

The following lemma establishes a concentration result for C_k with constant transmission power by coupling methods.

Lemma 2: For any $0 < \epsilon < 1$, the capacity of an s - t -cut of size k , $k = 0, 1, \dots, m$, satisfies

$$\Pr(C_k \leq (1 - \epsilon)E[C'_k]) \leq \exp \left\{ -\frac{E[C'_k]\epsilon^2}{2} \right\} \left(1 - O\left(\frac{1}{n}\right) \right) + O\left(\frac{1}{n}\right) \quad (18)$$

where $E[C'_k] = [m + k(m - k)]\bar{C}'$ and $\bar{C}'$ is the average link capacity in $G'(\mathcal{X}, P_0, \gamma)$. Moreover,

$$\Pr(C_k \geq (1 + \epsilon)E[C''_k]) \leq \exp \left\{ -\frac{E[C''_k]\epsilon^2}{3} \right\} \left(1 - O\left(\frac{1}{n}\right) \right) + O\left(\frac{1}{n}\right) \quad (19)$$

where $E[C''_k] = [m + k(m - k)]\bar{C}''$ and $\bar{C}''$ is the average link capacity in $G''(\mathcal{X}, P_0, \gamma)$.

Proof: By Lemma 1, for all j , $\{J(j) \geq (1 - \epsilon_1)E[J]\}$ and $\{J(j) \leq (1 + \epsilon'_1)E[J]\}$ are both increasing events.¹ By the FKG inequality [15], [26], [30], we have

$$\begin{aligned} \Pr \left(\bigcap_{j=1}^n \{J(j) \geq (1 - \epsilon_1)E[J]\} \right) &\geq \prod_{j=1}^n \Pr(J(j) \geq (1 - \epsilon_1)E[J]) \\ &= \left(1 - O\left(\frac{1}{n^2}\right) \right)^n \\ &= 1 - O\left(\frac{1}{n}\right), \end{aligned} \quad (20)$$

¹In the context of graph theory, an event A is called increasing if $I_A(G) \leq I_A(G')$ whenever graph G is a subgraph of G' , where I_A is the indicator function of A . An event A is called decreasing if A^c is increasing. For details, please see [15], [26], [30].

where the first equality is due to Lemma 1. Similarly,

$$\begin{aligned} \Pr\left(\bigcap_{j=1}^n \{J(j) \leq (1 + \epsilon'_1)E[J]\}\right) &\geq \prod_{j=1}^n \Pr(J(j) \leq (1 + \epsilon'_1)E[J]) \\ &= \left(1 - O\left(\frac{1}{n^2}\right)\right)^n \\ &= 1 - O\left(\frac{1}{n}\right). \end{aligned} \quad (21)$$

Inequalities (20) and (21) imply that

$$\Pr(C_k \leq C''_k) \geq 1 - O\left(\frac{1}{n}\right), \quad (22)$$

$$\Pr(C_k \geq C'_k) \geq 1 - O\left(\frac{1}{n}\right). \quad (23)$$

Since

$$\Pr(C_k \leq (1 - \epsilon)E[C'_k]) \leq 1 - \Pr(C_k \geq C'_k) \Pr(C'_k \geq (1 - \epsilon)E[C'_k]),$$

and

$$\Pr(C_k \geq (1 + \epsilon)E[C''_k]) \leq 1 - \Pr(C_k \leq C''_k) \Pr(C''_k \leq (1 + \epsilon)E[C''_k]),$$

in order to show (18) and (19), it suffices to show

$$\Pr(C'_k \leq (1 - \epsilon)E[C'_k]) \leq \exp\left\{-\frac{E[C'_k]\epsilon^2}{2}\right\}, \quad (24)$$

and

$$\Pr(C''_k \geq (1 + \epsilon)E[C''_k]) \leq \exp\left\{-\frac{E[C''_k]\epsilon^2}{3}\right\}. \quad (25)$$

In $G'(\mathcal{X}, P_0, \gamma)$ and $G''(\mathcal{X}, P_0, \gamma)$, the SINR of link (i, j) is given by (16) and (17), respectively. Because the d_{ij} 's for a given i are independent, by applying the Chernoff bounds, we obtain (24) and (25). $\square$

Since C'_{ij} and C''_{ij} are asymptotically equal to C_{ij} , $E[C'_k]$ and $E[C''_k]$ are asymptotically equal to $E[C_k]$. Consequently, Lemma 2 shows that C_k concentrates at $E[C_k]$ asymptotically almost surely.²

Now, let $C_{s,t}$ be the minimum cut capacity among all s - t -cuts, i.e.,

$$C_{s,t} = \min_{0 \leq k \leq m} C_k. \quad (26)$$

For one source and multiple destinations, the capacity of network coding depends on the minimum cut between the source and the destinations [11], [12], [17]. Therefore, for the given source node s and the sets of destination nodes $\mathcal{T} = \{t_1, \dots, t_l\}$ and relay nodes $\mathcal{R} = \{u_1, \dots, u_m\}$, define the network coding capacity as

$$C_{s,\mathcal{T}} = \min_{t \in \mathcal{T}} C_{s,t}. \quad (27)$$

²An event is said to be asymptotic almost sure (abbreviated a.a.s.) if it occurs with a probability converging to 1 as $n \rightarrow \infty$.

In the following, we show that when the number of relay nodes m is sufficiently large, the network coding capacity $C_{s,\mathcal{T}}$ concentrates at $E[C_0] = m\bar{C}$ with high probability.

Theorem 3: When n is sufficiently large, with high probability, the network coding capacity $C_{s,\mathcal{T}}$ satisfies

$$\Pr(C_{s,\mathcal{T}} \geq (1 - \epsilon'_\alpha)E[C_0]) = 1 - O\left(\frac{l}{m^\alpha}\right), \quad (28)$$

where $\epsilon'_\alpha = \sqrt{\frac{2\alpha \ln m}{E[C_0]}}$ for $\alpha > 0$ and $E[C_0] = m\bar{C}$.

Proof: Since the C_{ij} 's are asymptotically equal to the C'_{ij} 's, in order to show (28), it is equivalent to show

$$\Pr(C_{s,\mathcal{T}} \geq (1 - \epsilon'_\alpha)E[C'_0]) = 1 - O\left(\frac{l}{m^\alpha}\right).$$

Since $E[C'_k] \geq E[C'_0]$ for any $k = 1, \dots, m$,

$$\Pr(C_{s,t} \leq (1 - \epsilon'_\alpha)E[C'_0]) \leq \Pr(C_{s,t} \leq (1 - \epsilon'_\alpha)E[C'_{k'}]),$$

for any $t \in \mathcal{T}$, where k' is the size of the minimum s - t -cut. By (18) of Lemma 2, we have for sufficiently large n ,

$$\begin{aligned} \Pr(C_{s,t} \leq (1 - \epsilon'_\alpha)E[C'_{k'}]) &\leq \exp\left\{-\frac{\epsilon'^2_\alpha[m + k'(m - k')]\bar{C}'}{2}\right\} \\ &\leq \exp\left\{-\frac{\epsilon'^2_\alpha m \bar{C}'}{2}\right\}. \end{aligned}$$

By choosing $\epsilon'_\alpha = \sqrt{\frac{2\alpha \ln m}{E[C_0]}}$, since $\bar{C}'$ and $\bar{C}$ are asymptotically equal, we have for any $t \in \mathcal{T}$,

$$\Pr(C_{s,t} \leq (1 - \epsilon'_\alpha)E[C'_0]) = O\left(\frac{1}{m^\alpha}\right).$$

By the union bound, we have

$$\begin{aligned} \Pr(C_{s,\mathcal{T}} \leq (1 - \epsilon'_\alpha)E[C'_0]) &\leq \sum_{t \in \mathcal{T}} \Pr(C_{s,t} \leq (1 - \epsilon'_\alpha)E[C'_0]) \\ &= O\left(\frac{l}{m^\alpha}\right). \end{aligned}$$

□

Theorem 4: When n is sufficiently large, with high probability, the network coding capacity $C_{s,\mathcal{T}}$ satisfies

$$\Pr(C_{s,\mathcal{T}} \leq (1 + \epsilon''_\alpha)E[C_0]) = 1 - O\left(\frac{1}{m^\alpha}\right), \quad (29)$$

where $\epsilon''_\alpha = \sqrt{\frac{3\alpha \ln m}{E[C_0]}}$ for $\alpha > 0$ and $E[C_0] = m\bar{C}$.

Proof: Since the C_{ij} 's are asymptotically equal to the C_{ij}'' 's, in order to show (29), it is equivalent to show

$$\Pr(C_{s,\mathcal{T}} \leq (1 + \epsilon''_\alpha)E[C_0'']) = 1 - O\left(\frac{1}{m^\alpha}\right).$$

To show this, it is sufficient to consider a particular cut for a source-destination pair, e.g., an s - t -cut with capacity $\sum_{i=1}^m C_{si}$ separating the source s from all the other nodes.

$$\begin{aligned} \Pr(C_{s,\mathcal{T}} \geq (1 + \epsilon''_\alpha)E[C_0'']) &\leq \Pr(C_{s,t} \geq (1 + \epsilon''_\alpha)E[C_0'']) \\ &\leq \Pr\left(\sum_{i=1}^m C_{si} \geq (1 + \epsilon''_\alpha)E[C_0'']\right) \\ &= \Pr(C_0 \geq (1 + \epsilon''_\alpha)E[C_0'']) \\ &\leq \exp\left(-\frac{\epsilon''_\alpha{}^2 m \bar{C}''}{3}\right) \\ &= O\left(\frac{1}{m^\alpha}\right). \end{aligned}$$

where the last inequality follows from (19). $\square$

C. Heterogeneous Transmission Powers

In this subsection, we consider the case where the transmission power of each node is randomly chosen rather than being constant. We continue to assume that the capacity of a link (i, j) is a constant R , which is independent of the SINR β_{ij} , when $\beta_{ij} \geq \beta$. In this case, β_{ij} can be rewritten as

$$\begin{aligned} \beta_{ij} &= \frac{P_i L(d_{ij})}{N_0 + \gamma \sum_{k \neq i,j} P_k L(d_{kj})} \\ &= \frac{P_i L(d_{ij})}{N_0 + \gamma I(j) - \gamma P_i L(d_{ij})}. \end{aligned} \tag{30}$$

Because the P_i 's and $\mathbf{X}_i$'s are both i.i.d., using the same technique as that for Lemma 1, we can prove the following lemma.

Lemma 5: Suppose there are n nodes in the network, then

$$\Pr(I(j) \leq (1 - \epsilon_2)E[I]) = O\left(\frac{1}{n^2}\right), \tag{31}$$

and

$$\Pr(I(j) \geq (1 + \epsilon'_2)E[I]) = O\left(\frac{1}{n^2}\right), \tag{32}$$

for all $j = 1, 2, \dots, n$, where $\epsilon_2 = \sqrt{\frac{4 \ln n}{(n-1)E[P]E[L]}}$ and $\epsilon'_2 = \sqrt{\frac{6 \ln n}{(n-1)E[P]E[L]}}$.

Even though we have concentration results for $I(j)$, we cannot employ the same coupling methods as in the previous section. In $G'(\mathcal{X}, P_0, \gamma)$ (or $G''(\mathcal{X}, P_0, \gamma)$) as described in Section III-B, the C_{ij}' 's (or C_{ij}'' 's) are independent for all $j \neq i$ for a given i . In our new case, however, this independence does not

hold because all the C_{ij} 's depend on the transmission power P_i . To deal with this dependence, we use martingale methods and Azuma's inequality to solve our problem.

Theorem 6 (Azuma's Inequality [30]): Let $Z_0, Z_1, \dots$, be a martingale sequence such that for each $i = 1, 2, \dots$,

$$|Z_i - Z_{i-1}| \leq c_i$$

almost surely, where c_i may depend on i . Then for all $n > 0$ and any $\lambda > 0$,

$$\Pr(Z_n \geq Z_0 + \lambda) \leq \exp \left\{ -\frac{\lambda^2}{2 \sum_{i=1}^n c_i^2} \right\}, \quad (33)$$

and

$$\Pr(Z_n \leq Z_0 - \lambda) \leq \exp \left\{ -\frac{\lambda^2}{2 \sum_{i=1}^n c_i^2} \right\}. \quad (34)$$

Proof: Please see e.g. [30]. □

To use Azuma's inequality, we need to construct a martingale. A common approach to obtain a martingale from a sequence of (not necessarily independent) random variables is to construct a Doob sequence. Specifically, suppose we have a sequence of random variables $Y_1, Y_2, \dots, Y_n$, which are not necessarily independent. Let $S = \sum_{i=1}^n Y_i$ and define a new sequence of random variables $\{Z_i : i = 0, 1, \dots, n\}$ by:

$$\begin{cases} Z_0 &= E[S] \\ Z_i &= E_{Y_{i+1}, \dots, Y_n}[S | Y_1, \dots, Y_i], \quad i = 1, 2, \dots, n. \end{cases} \quad (35)$$

Then $\{Z_i : i = 0, 1, \dots, n\}$ is a martingale and $Z_n = S$.

If we are able to upper bound the difference $|Z_i - Z_{i-1}|$ for all i by some constant, then we can apply Azuma's inequality to obtain a bound on the tail probability. For example, if the Y_i 's are independent, a simple upper bound for $|Z_i - Z_{i-1}|$ is any upper bound on $|Y_i|$. However, if the Y_i 's are dependent, we need to further understand the properties of the Y_i 's to bound $|Z_i - Z_{i-1}|$. We approach our problem by following this idea and using the next corollary.

Lemma 7: For $n > 1$, given a sequence of random variables $Y_1, Y_2, \dots, Y_n$, which are not necessarily independent, let $S = \sum_{i=1}^n Y_i$. If for any $y_i, y'_i \in D_i$, where D_i is the support of Y_i ,

$$|E[S | Y_1, \dots, Y_{i-1}, Y_i = y_i] - E[S | Y_1, \dots, Y_{i-1}, Y_i = y'_i]| \leq c_i,$$

almost surely, where c_i may depend on i , then for any $\lambda > 0$,

$$\Pr(S \geq E[S] + \lambda) \leq \exp \left\{ -\frac{\lambda^2}{2 \sum_{i=1}^n c_i^2} \right\}, \quad (36)$$

and

$$\Pr(S \leq E[S] - \lambda) \leq \exp \left\{ -\frac{\lambda^2}{2 \sum_{i=1}^n c_i^2} \right\}. \quad (37)$$

Proof: We prove this corollary for the case of discrete random variables. For continuous random variables, the proof is similar.

Define a Doob sequence with respect to $\{Y_i : i = 1, \dots, n\}$ as in (35). To simplify notation, we will write $E_{Y_{i+1}, \dots, Y_n}[S|Y_1, \dots, Y_i]$ as $E[S|Y_1, \dots, Y_i]$ when there is no ambiguity.

By the total conditional probability theorem, we have

$$\begin{aligned} Z_{i-1} &= E[S|Y_1, \dots, Y_{i-1}] \\ &= \sum_{y \in D_i} E[S|Y_1, \dots, Y_{i-1}, Y_i = y] \Pr(Y_i = y|Y_1, \dots, Y_{i-1}), \end{aligned}$$

and

$$\begin{aligned} Z_i &= E[S|Y_1, \dots, Y_i] \\ &= \sum_{y \in D_i} E[S|Y_1, \dots, Y_i] \Pr(Y_i = y|Y_1, \dots, Y_{i-1}). \end{aligned}$$

Therefore,

$$\begin{aligned} &|Z_i - Z_{i-1}| \\ &= \left| \sum_{y \in D_i} E[S|Y_1, \dots, Y_i] \Pr(Y_i = y|Y_1, \dots, Y_{i-1}) - \sum_{y \in D_i} E[S|Y_1, \dots, Y_{i-1}, Y_i = y] \Pr(Y_i = y|Y_1, \dots, Y_{i-1}) \right| \\ &\leq \sum_{y \in D_i} |E[S|Y_1, \dots, Y_i] - E[S|Y_1, \dots, Y_{i-1}, Y_i = y]| \Pr(Y_i = y|Y_1, \dots, Y_{i-1}) \\ &\leq \sum_{y \in D_i} c_i \Pr(Y_i = y|Y_1, \dots, Y_{i-1}) \\ &= c_i. \end{aligned}$$

Since $\{Z_i : i = 0, 1, \dots, n\}$ is a martingale with bounded difference of $|Z_i - Z_{i-1}|$, we can apply Azuma's inequality to obtain (36) and (37). $\square$

Now consider $G'(\mathcal{X}, \mathcal{P}, \gamma)$ and $G''(\mathcal{X}, \mathcal{P}, \gamma)$ coupled with $G(\mathcal{X}, \mathcal{P}, \gamma)$ such that they have the same point process $\mathcal{X}$ and powers $\mathcal{P}$, where the SINR's of link (i, j) in $G'(\mathcal{X}, \mathcal{P}, \gamma)$ and $G''(\mathcal{X}, \mathcal{P}, \gamma)$ are

$$\beta'_{ij} = \frac{P_i L(d_{ij})}{N_0 + (1 + \epsilon'_2) \gamma E[I] - \gamma P_i L(d_{ij})} \quad (38)$$

and

$$\beta''_{ij} = \frac{P_i L(d_{ij})}{N_0 + (1 - \epsilon_2) \gamma E[I] - \gamma P_i L(d_{ij})}, \quad (39)$$

respectively.

Let C'_{ij} and C''_{ij} be the capacity of link (i, j) in $G'(\mathcal{X}, \mathcal{P}, \gamma)$ and $G''(\mathcal{X}, \mathcal{P}, \gamma)$, respectively. Then, C'_{ij} and C''_{ij} are asymptotically equal to C_{ij} .

Assume that there exist positive solutions $r'_{min} > 0$, $r'_{max} > 0$, $r''_{min} > 0$ and $r''_{max} > 0$ for the equations

$$\frac{p_{min} L(r'_{min})}{N_0 + \gamma(1 + \epsilon'_2) E[I] - \gamma p_{min} L(r'_{min})} = \beta,$$

$$\frac{p_{\max} L(r'_{\max})}{N_0 + \gamma(1 + \epsilon'_2)E[I] - \gamma p_{\max} L(r'_{\max})} = \beta,$$

$$\frac{p_{\min} L(r''_{\min})}{N_0 + \gamma(1 - \epsilon_2)E[I] - \gamma p_{\min} L(r''_{\min})} = \beta,$$

and

$$\frac{p_{\max} L(r''_{\max})}{N_0 + \gamma(1 - \epsilon_2)E[I] - \gamma p_{\max} L(r''_{\max})} = \beta,$$

respectively. That is

$$\begin{aligned} r'_{\min} &= L^{-1} \left(\frac{\beta}{1 + \gamma\beta} \cdot \frac{N_0 + \gamma(1 + \epsilon'_2)E[I]}{p_{\min}} \right), \\ r'_{\max} &= L^{-1} \left(\frac{\beta}{1 + \gamma\beta} \cdot \frac{N_0 + \gamma(1 + \epsilon'_2)E[I]}{p_{\max}} \right), \\ r''_{\min} &= L^{-1} \left(\frac{\beta}{1 + \gamma\beta} \cdot \frac{N_0 + \gamma(1 - \epsilon_2)E[I]}{p_{\min}} \right), \\ r''_{\max} &= L^{-1} \left(\frac{\beta}{1 + \gamma\beta} \cdot \frac{N_0 + \gamma(1 - \epsilon_2)E[I]}{p_{\max}} \right). \end{aligned}$$

Since $L(\cdot)$ is continuous and strictly decreasing, $r'_{\min}$, $r'_{\max}$, $r''_{\min}$ and $r''_{\max}$ are all unique. In $G'(\mathcal{X}, \mathcal{P}, \gamma)$ ($G''(\mathcal{X}, \mathcal{P}, \gamma)$), any node inside the circle centered at $\mathbf{X}_i$ with radius $r'_{\min}$ ($r''_{\min}$) is connected to node i by a bidirectional link, while any node outside the circle centered at $\mathbf{X}_i$ with radius $r'_{\max}$ ($r''_{\max}$) is not connected to node i .

Let $\mathcal{A}(\mathbf{X}_i, r'_{\min}, r'_{\max})$ and $\mathcal{A}(\mathbf{X}_i, r''_{\min}, r''_{\max})$ be the two annuli with inner radius $r'_{\min}$ and outer radius $r'_{\max}$, and inner radius $r''_{\min}$ and outer radius $r''_{\max}$, respectively. Denote by $N(r'_{\min}, r'_{\max})$ and $N(r''_{\min}, r''_{\max})$ the number of nodes in $\mathcal{A}(\mathbf{X}_i, r'_{\min}, r'_{\max})$ and $\mathcal{A}(\mathbf{X}_i, r''_{\min}, r''_{\max})$, respectively. It is clear that $N(r'_{\min}, r'_{\max})$ and $N(r''_{\min}, r''_{\max})$ are binomially distributed with mean $n\pi(r'^2_{\max} - r'^2_{\min})$ and $n\pi(r''^2_{\max} - r''^2_{\min})$, respectively.

Now suppose the signal attenuation function $L(x) = cx^{-\alpha}$ for some constants $c > 0$ and $2 < \alpha < 4$. Then,

$$\begin{aligned} r'_{\min} &= \left(\frac{c(1 + \gamma\beta)p_{\min}}{\beta[N_0 + \gamma(1 + \epsilon'_2)E[I]]} \right)^{1/\alpha}, \\ r'_{\max} &= \left(\frac{c(1 + \gamma\beta)p_{\max}}{\beta[N_0 + \gamma(1 + \epsilon'_2)E[I]]} \right)^{1/\alpha}, \\ r''_{\min} &= \left(\frac{c(1 + \gamma\beta)p_{\min}}{\beta[N_0 + \gamma(1 - \epsilon_2)E[I]]} \right)^{1/\alpha}, \\ r''_{\max} &= \left(\frac{c(1 + \gamma\beta)p_{\max}}{\beta[N_0 + \gamma(1 - \epsilon_2)E[I]]} \right)^{1/\alpha}, \end{aligned}$$

and

$$r'^2_{\max} - r'^2_{\min} = \frac{B(p_{\min}, p_{\max})}{[N_0 + \gamma(1 + \epsilon'_2)E[I]]^{2/\alpha}}, \quad (40)$$

$$r''^2_{\max} - r''^2_{\min} = \frac{B(p_{\min}, p_{\max})}{[N_0 + \gamma(1 - \epsilon_2)E[I]]^{2/\alpha}}, \quad (41)$$

where

$$B(p_{\min}, p_{\max}) = (p_{\max}^{2/\alpha} - p_{\min}^{2/\alpha}) \left[\frac{c(1 + \gamma\beta)}{\beta} \right]^{2/\alpha}. \quad (42)$$

From (40) and (41), we can see that both $n\pi(r_{\max}'^2 - r_{\min}'^2)$ and $n\pi(r_{\max}''^2 - r_{\min}''^2)$ scale with n as $\frac{B}{n^{2/\alpha-1}}$, since $E[I] = (n-1)E[P]E[I]S$ scales linearly with n . Now assume that there exists a constant $\eta > 0$ independent of n such that

$$N(r_{\min}', r_{\max}') \leq \eta, \quad \text{and} \quad N(r_{\min}'', r_{\max}'') \leq \eta \quad (43)$$

a.a.s. This assumption effectively puts a constraint on the transmission power. For example, if we choose $\eta = 1$, then the transmission power P must scale with n so that $p_{\max} = O(n^{1-\alpha/2})$. Note that $r_{\min}'$ and $r_{\max}'$ are asymptotically equal to $r_{\min}''$ and $r_{\max}''$, respectively.

The following lemma establishes a concentration result for C_k with heterogeneous transmission power and constant capacity by coupling methods and Azuma's inequality.

Lemma 8: For any $0 < \epsilon < 1$, when n is sufficiently large and (43) is guaranteed, with high probability, the capacity of an s - t -cut of size k , $k = 0, 1, \dots, m$, satisfies

$$\Pr(C_k \leq (1 - \epsilon)E[C_k']) \leq \exp \left\{ -\frac{[m + k(m - k)]\bar{C}'^2\epsilon^2}{2\eta^2 R^2} \right\}, \quad (44)$$

where $E[C_k'] = [m + k(m - k)]\bar{C}'$ and $\bar{C}'$ is the average link capacity in $G'(\mathcal{X}, \mathcal{P}, \gamma)$. Moreover,

$$\Pr(C_k \geq (1 + \epsilon)E[C_k'']) \leq \exp \left\{ -\frac{[m + k(m - k)]\bar{C}''^2\epsilon^2}{2\eta^2 R^2} \right\}, \quad (45)$$

where $E[C_k''] = [m + k(m - k)]\bar{C}''$ and $\bar{C}''$ is the average link capacity in $G''(\mathcal{X}, \mathcal{P}, \gamma)$.

Proof: By Lemma 5, for all j , $(1 - \epsilon_2)E[I] \leq I(j) \leq (1 + \epsilon_2')E[I]$ holds a.a.s. As in the proof for Lemma 2, we have that C_k is lower bounded by C_k' , and upper bounded by C_k'' , with probability at least $1 - O(1/n)$. Hence, in order to show (44) and (45), it suffices to show

$$\Pr(C_k' \leq (1 - \epsilon)E[C_k']) \leq \exp \left\{ -\frac{[m + k(m - k)]\bar{C}'^2\epsilon^2}{2\eta^2 R^2} \right\} \quad (46)$$

and

$$\Pr(C_k'' \geq (1 + \epsilon)E[C_k'']) \leq \exp \left\{ -\frac{[m + k(m - k)]\bar{C}''^2\epsilon^2}{2\eta^2 R^2} \right\}. \quad (47)$$

To show (46), we use martingale methods. Let $Y_1 = C_{s(k+1)}'$, $Y_2 = C_{s(k+2)}'$, ..., $Y_{m-k} = C_{sm}'$, $Y_{m-k+1} = C_{1(k+1)}'$, $Y_{m-k+2} = C_{1(k+2)}'$, ..., $Y_{m-k+k(m-k)} = C_{km}'$, and $Y_{m-k+k(m-k)+1} = C_{1t}'$, $Y_{m-k+k(m-k)+2} = C_{2t}'$, ..., $Y_{m-k+k(m-k)+k} = C_{kt}'$. Define a Doob sequence $\{Z_i : i = 0, \dots, m + k(m - k)\}$ with respect to $\{Y_i, i = 1, 2, \dots, m + k(m - k)\}$ as

$$\begin{cases} Z_0 &= E[C_k'] \\ Z_i &= E[C_k' | Y_1, \dots, Y_i], \quad i = 1, 2, \dots, m + k(m - k). \end{cases}$$

Then $\{Z_i : i = 0, \dots, m + k(m - k)\}$ is a martingale and $Z_{m+k(m-k)} = C_k'$.

Since when $i \neq u$ and $j \neq v$, C'_{ij} is independent of C'_{uv} , dependence exists only among C'_{ij} 's, $j \neq i$, for a given i . However, the distances d_{ij} are independent for all $j \neq i$ for given i . Hence the difference between $E[C'_k|Y_1, \dots, Y_{l-1}, Y_l = y_l]$ and $E[C'_k|Y_1, \dots, Y_{l-1}, Y_l = y'_l]$ depends only on those Y_h 's which are incident on the same source node as Y_l . When $d_{ij} \leq r'_{min}$, $C'_{ij} = R$, and when $d_{ij} > r'_{max}$, $C'_{ij} = 0$. Moreover, the number of nodes within the annulus $\mathcal{A}(\mathbf{X}_i, r'_{min}, r'_{max})$ is upper bounded by the constant η a.a.s. Therefore,

$$|E[C'_k|Y_1, \dots, Y_{l-1}, Y_l = y_l] - E[C'_k|Y_1, \dots, Y_{l-1}, Y_l = y'_l]| \leq \eta R$$

a.a.s., where y_l and y'_l are either 0 or R .

Applying the result of Lemma 7, we have (46). In the same manner, we can show that (47) holds. $\square$

In the following, we show that when the number of relay nodes m is sufficiently large, the network coding capacity $C_{s,\mathcal{T}}$ concentrates at $E[C_0] = m\bar{C}$ with high probability. The proofs are based on Lemma 8 and very similar to those for Theorem 3 and Theorem 4, and provided here for completeness.

Theorem 9: When n is sufficiently large, with high probability, the network coding capacity $C_{s,\mathcal{T}}$ satisfies

$$\Pr(C_{s,\mathcal{T}} \geq (1 - \epsilon_\alpha)E[C_0]) = 1 - O\left(\frac{l}{m^\alpha}\right), \quad (48)$$

where $\epsilon_\alpha = \frac{\eta R}{E[C_0]} \sqrt{2\alpha m \ln m}$ for $\alpha > 0$ and $E[C_0] = m\bar{C}$.

Proof: Since the C_{ij} 's are asymptotically equal to the C'_{ij} 's, in order to show (48), it is equivalent to show

$$\Pr(C_{s,\mathcal{T}} \geq (1 - \epsilon_\alpha)E[C'_0]) = 1 - O\left(\frac{l}{m^\alpha}\right).$$

Since $E[C'_k] \geq E[C'_0]$ for any $k = 1, \dots, m$,

$$\Pr(C_{s,t} \leq (1 - \epsilon_\alpha)E[C'_0]) \leq \Pr(C_{s,t} \leq (1 - \epsilon_\alpha)E[C'_{k'}]),$$

for any $t \in \mathcal{T}$, where k' is the size of the minimum s - t -cut. By (44) of Lemma 8, we have

$$\begin{aligned} \Pr(C_{s,t} \leq (1 - \epsilon_\alpha)E[C'_{k'}]) &\leq \exp \left\{ -\frac{\epsilon_\alpha^2 [m + k'(m - k')] \bar{C}'^2}{2(\eta + 1)^2 R^2} \right\} \\ &\leq \exp \left\{ -\frac{\epsilon_\alpha^2 m \bar{C}'^2}{2(\eta + 1)^2 R^2} \right\}. \end{aligned}$$

By choosing $\epsilon_\alpha = \frac{(\eta+1)R}{E[C_0]} \sqrt{2\alpha m \ln m}$ for $\alpha > 0$, since $\bar{C}'$ and $\bar{C}$ are asymptotically equal, for any $t \in \mathcal{T}$,

$$\Pr(C_{s,t} \leq (1 - \epsilon_\alpha)E[C'_0]) = O\left(\frac{1}{m^\alpha}\right).$$

By the union bound, we have

$$\begin{aligned} \Pr(C_{s,\mathcal{T}} \leq (1 - \epsilon_\alpha)E[C'_0]) &\leq \sum_{t \in \mathcal{T}} \Pr(C_{s,t} \leq (1 - \epsilon_\alpha)E[C'_0]) \\ &= O\left(\frac{l}{m^\alpha}\right). \end{aligned}$$

□

Theorem 10: When n is sufficiently large, with high probability, the network coding capacity $C_{s,\mathcal{T}}$ satisfies

$$\Pr(C_{s,\mathcal{T}} \leq (1 + \epsilon_\alpha)E[C_0]) = 1 - O\left(\frac{1}{m^\alpha}\right), \quad (49)$$

where $\epsilon_\alpha = \frac{\eta R}{E[C_0]} \sqrt{2\alpha m \ln m}$ for $\alpha > 0$ and $E[C_0] = m\bar{C}$.

Proof: Since the C_{ij} 's are asymptotically equal to C''_{ij} 's, in order to show (49), it is equivalent to show

$$\Pr(C_{s,\mathcal{T}} \leq (1 + \epsilon_\alpha)E[C''_0]) = 1 - O\left(\frac{1}{m^\alpha}\right).$$

To show this, it is sufficient to consider a particular cut for a pair of the source and one destination, for instance, an s - t -cut separating the source s from all the other nodes.

$$\begin{aligned} \Pr(C_{s,\mathcal{T}} \geq (1 + \epsilon_\alpha)E[C''_0]) &\leq \Pr(C_{s,t} \geq (1 + \epsilon_\alpha)E[C''_0]) \\ &\leq \Pr\left(\sum_{i=1}^m C_{si} \geq (1 + \epsilon_\alpha)E[C''_0]\right) \\ &= \Pr(C_0 \geq (1 + \epsilon_\alpha)E[C''_0]) \\ &\leq \exp\left\{-\frac{\epsilon_\alpha^2 m \bar{C}''^2}{2(\eta + 1)^2 R^2}\right\} \\ &= O\left(\frac{1}{m^\alpha}\right). \end{aligned}$$

where the last inequality follows from (45) of Lemma 8. □

IV. SIMULATION STUDIES

In this section, we present some simulation results on the SINR model and the network coding capacity. Fig. 3 and Fig. 4 show simulation results on interference and cut capacity in $G(\mathcal{X}, P_0, \gamma)$, where $n = 2000$, $L(x) = \frac{10^{-3}}{64}x^{-3}$, $N_0 = 0.02$, $\beta = 0.2$ and $\gamma = 0.02$, and every node transmits with constant power $P_0 = 0.01$. Fig. 5 and Fig. 6 show simulation results on the interference and the cut capacity in $G(\mathcal{X}, \mathcal{P}, \gamma)$, where $n = 2000$, $L(x) = \frac{10^{-3}}{64}x^{-3}$, $N_0 = 0.02$, $\beta = 0.2$ and $\gamma = 0.02$, and every node transmits with power P uniformly randomly distributed over $[0.01, 0.02]$. The results confirm the concentration behavior of the interference and the cut capacity.

Fig. 3. Interference at each node, and capacity of random s - t -cut of size $k = 50$ in $G(\mathcal{X}, P_0, \gamma)$

Fig. 4. Interference at each node, and capacity of random s - t -cut of size $k = 50$ in $G(\mathcal{X}, \mathcal{P}, \gamma)$

V. CONCLUSIONS

In this paper, we studied the network coding capacity for random wireless networks under a SINR model, where the network is modelled by the graph $G(\mathcal{X}, \mathcal{P}, \gamma)$. Previous work on the network coding capacity for random wired/wireless networks are based on the assumption that the capacities of links are independent. In the SINR model, however, the capacities of links are not independent due to noise and interference. We investigated two scenarios. In the first case $G(\mathcal{X}, P_0, \gamma)$, we assumed all nodes transmit with a constant power P_0 . To study the network coding capacity in $G(\mathcal{X}, P_0, \gamma)$, we coupled $G(\mathcal{X}, P_0, \gamma)$ with two other models $G'(\mathcal{X}, P_0, \gamma)$ and $G''(\mathcal{X}, P_0, \gamma)$, which have the same point process $\mathcal{X}$ and constant power P_0 , but different thresholds. We showed that the network coding capacity for $G(\mathcal{X}, P_0, \gamma)$ is upper and lower bounded by those for $G'(\mathcal{X}, P_0, \gamma)$ and $G''(\mathcal{X}, P_0, \gamma)$. By proving that the network coding capacities for $G'(\mathcal{X}, P_0, \gamma)$ and $G''(\mathcal{X}, P_0, \gamma)$ concentrate on the same value asymptotically, we showed that when the size of the network is sufficiently large, the network coding capacity for $G(\mathcal{X}, P_0, \gamma)$ exhibits a concentration behavior around the mean value of the minimum cut. In the second case $G(\mathcal{X}, \mathcal{P}, \gamma)$, we assumed each node transmits with a random power drawn from some distribution. Since coupling methods

could not be applied in this general case, we used martingale techniques to deal with dependence between link capacities, and showed that under some mild conditions, the network coding capacity also exhibits a concentration behavior. The results obtained are important for understanding network coding performance in random wireless networks under the SINR model. In addition, the methods used in this paper provide useful techniques for studying properties of random wireless networks under the SINR model.
